

Machine Learning

---

# Logistic Regression

# Linear Regression and Logistic Regression

---

- Logistic regression uses Sigmoid function to make probabilistic prediction. Probability  $P$  that a data point belongs to a class for a given value of  $x$
- Probability value is between 0 and 1

# Linear Regression and Logistic Regression

---

- As  $X$  increases, the probability value increases. As  $x$  tends to infinity, the probability becomes 1
- As value of  $X$  decreases, the probability decreases. As  $x$  tends to negative infinity, the probability becomes 0

# Optimization function for Logistic Regression

---

Maximise Likelihood:  $L = \prod P^{y_i} * (1-P)^{(1-y_i)}$

Maximise Likelihood  $\Rightarrow$  Maximize  $\text{Log}(\text{Likelihood})$

$$\text{Log}(\text{Likelihood}) = \sum ( y_i \log(P) + (1-y_i) \log(1-P) )$$

# EXTRA SLIDE... Log Likelihood

$$\text{Log(Likelihood)} = \sum (y_i \log(P) + (1-y_i) \log(1-P))$$

p	Ln(p)	Change in value
0.0000001	-16.1181	Smaller

## EXTRA SLIDE...Odds

---

$$P = \frac{1}{1+e^{-(z)}}$$

$$1 - P = \frac{1}{1 + e^z}$$

$$\frac{P}{1-P} = e^z$$

$$Odds = \frac{P}{1-P} = e^z \qquad P = \frac{Odds}{1+Odds}$$

$$\text{Log(Odds)} = z = (b_0 + b_1 * x_1 + \dots)$$

## EXTRA SLIDE... Log(Odds)

---

- Another way to interpret logistic regression

$$\log \frac{p(x)}{1 - p(x)} = \beta_0 + x \cdot \beta$$

<u>Value of <math>p</math></u>	<u>Odds of <math>p</math></u>
0.9	9:1
0.8	4:1
0.6	1.5:1
0.5	1:1
0.4	0.67:1
0.2	0.25:1
0.1	0.11:1

## EXTRA SLIDE... Odds Ratio

---

$$\text{Odds}_{x_1} = e^{(b_0 + b_1 * x_1 + \dots)}$$

$$\text{Odds}_{x_1+1} = e^{(b_0 + b_1 * (x_1+1) + \dots)}$$

$$\text{Odds ratio} = \frac{\text{Odds}_{x_1+1}}{\text{Odds}_{x_1}} = e^{b_1}$$

If  $b_1 = 1.5$ , then for every unit increase in  $x_1$  (having all other  $X$ s unchanged), the odds will increase  $e^{1.5}$  times

What will be the case when  $b_1$  is negative?

# Logistic Regression

---

## Advantages -

- Efficient algorithm, does not require too many computational resources
  - Fast in training
  - Very fast in classifying unknown records
- Probabilistic view used in the method is easy to understand
- No assumptions about distributions of variables are made
- Extended to multiple classes
- Good accuracy for many simple data sets
- Resistant to overfitting

## Disadvantages -

- Underperforms where there are more complex relationships requiring non-linear boundaries

# Confusion Matrix

---

		Predicted		
		A	B	C
Actual	A	15	0	0
	B	0	19	2
	C	0	0	17

- Classification accuracy = correct predictions / total predictions
- Precision is the proportion of the predicted positive cases that were correct.
  - Precision of C =  $17 / (17+2)$
- Recall is the proportion of positive cases that were correctly identified
  - Recall for B =  $19 / (19+2)$
- F1 Score =  $2 * (\text{Recall} * \text{Precision}) / (\text{Recall} + \text{Precision})$

# Confusion Matrix

		Predicted	
		Positive	Negative
Actual	Positive	TP	FN
	Negative	FP	TN

		Predicted	
		Negative	Positive
Actual	Negative	TN	FP
	Positive	FN	TP

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}$$

$$\text{Recall} = \frac{TP}{TP + FN}$$

$$\text{Precision} = \frac{TP}{TP + FP}$$

- True Positive (TP) : Observation is positive, and is predicted to be positive.
- False Negative (FN) : Observation is positive, but is predicted negative.
- True Negative (TN) : Observation is negative, and is predicted to be negative.
- False Positive (FP) : Observation is negative, but is predicted positive.
- Note that in binary classification, **recall of the positive** class is also known as “**sensitivity**”; and **recall of the negative** class is “**specificity**”.
- High recall, low precision: This means that most of the positive examples are correctly recognized (low FN) but there are a lot of false positives.
- Low recall, high precision: This shows that we miss a lot of positive examples (high FN) but those we predict as positive are indeed positive (low FP)
